Logging Service Redesign

- This Redesign will import the logging services as a submodule which can be imported and used with any project

- Firstly we will have a LogChunk<T> object which will be a template / generic This object will handle packing data into sizeable chunks in order to log them into flash. Data size will be stored so step is identified when reading back. Size is determined by <T>, getters will return data type and size. Make <T> will create the chunk

- Next FlashLogger, this will log data to flash using same logic. Using LogChunk<T> will save wasted space from 20 byte chunks. Chunks will fill into 512 byte buffers padded with 0xFF to fill. Will have to add does not fit logic as well as flush and pad logic

- Next is the LogReader objects. This will be decoupled from FlashLogger which will improve code quality. Same readback logic will be applied. Difference is varying chunk sizes which could make flash recovery harder if one chunk is messed up, a whole sector would be cooked. Thats the only downfall as it can be used separate of the Reader.

- FlashCursor will be an object that stores the Flash cursor. This will be used to track the flash cursor
